Problem 3.8 In Ex. 3.2 we assumed that the conducting sphere was grounded \((V = 0)\). But with the addition of a second image charge, the same basic model will handle the case of a sphere at any potential \(V_0\) (relative, of course, to infinity). What charge should you use, and where should you put it? Find the force of attraction between a point charge \(q\) and a neutral conducting sphere.

Example 3.2

A point charge \(q\) is situated a distance \(a\) from the center of a grounded conducting sphere of radius \(R\) (Fig. 3.12). Find the potential outside the sphere.

![Diagram of a sphere and point charge](image)

\[ V = 0 \]

\[ q \]

\[ a \]

Solution: Examine the completely different configuration, consisting of the point charge \(q\) together with another point charge \(q' = -\frac{R}{a} q\) placed \(\delta\) to the right of the center of the sphere (Fig. 3.13). No conductor, now—just the two point charges. The potential of this configuration is

\[ V(r) = \frac{1}{4\pi\varepsilon_0} \left( \frac{q}{r} + \frac{q'}{r'} \right), \quad (3.17) \]

where \(r\) and \(r'\) are the distances from \(q\) and \(q'\), respectively. Now, it happens (see Prob. 3.7) that this potential vanishes at all points on the sphere, and therefore fits the boundary conditions for our original problem, in the exterior region.

To increase the potential by \(V_0\), recall that the potential of a point charge is \(V = \frac{q\varepsilon_0}{4\pi\varepsilon_0 r}\), so just put a point charge \(q_0 = V_0\varepsilon_0 R\) at the center of the sphere.
Problem 3.2 In one sentence, justify Earnshaw's Theorem: a charged particle cannot be held in stable equilibrium by electrostatic forces alone. As an example, consider the cubical lattice of fixed charges in Fig. 3.4. It looks, offhand, as though a positive charge at the center would be suspended in midair—repelled away from each corner. Where is the leak in this "electrostatic bottle"? (To harness nuclear fusion as a practical energy source it is necessary to heat a plasma (soup of charged particles) to fantastic temperatures—so hot that contact would vaporize any ordinary pot. Earnshaw's Theorem says that electrostatic containment is also out of the question. Fortunately, it is possible to confine a hot plasma magnetically."

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{cube.png}
\caption{Figure 3.4}
\end{figure}

Stable equilibria occur at potential energy minima \((U < qV)\), but solutions of \(\nabla^2 V = 0\) \((\nabla)\) can have no local minima, therefore any electrostatic equilibrium must be unstable. \(\nabla \cdot (\nabla V) = \nabla^2 V = 0\)

For example, the center point above, all faces cancel—it is a point of equilibrium. But this equilibrium is unstable—a small displacement (of a test charge) from the center of the cube results in a force imbalance.

\[\begin{align*}
F_x &
\rightarrow 0 & F_z &
\rightarrow 0 & F_{xw} &
\leftarrow F_{wz} \\
\text{is in the} & & \text{direction of the} & & \text{displacement,}\, \text{the displacement grows,}\, \text{...}
\end{align*}\]

\(V\) cannot have a minimum at the center of cube—it must be in some sort of saddle point.

UNSTABLE EQUILIBRIUM
Problem 2.22 Find the potential a distance \( r \) from an infinitely long straight wire that carries a uniform line charge \( \lambda \). Compute the gradient of your potential, and check that it yields the correct field.

\[
\frac{1}{r^2} E_r = E_0
\]

\[
\lambda = \frac{d\lambda}{dr}
\]

Flux through Gaussian cylinder \( \Phi E \cdot d\vec{a} = \frac{\lambda}{\varepsilon_0} \)

\[
E(\rho) = \frac{\lambda}{2\pi \varepsilon_0} \rho
\]

\[
V(\rho) = -\int E \cdot d\vec{l} = -\frac{2}{2\pi \varepsilon_0} \int_0^\rho \frac{d\rho}{\rho} = -\frac{2}{2\pi \varepsilon_0} (ln \rho_0 - ln \rho)
\]

BC: Fix reference point at \( a \): \( V(a) = 0 \)

Can’t choose \( V(a) = 0 \) because \( a \) extends to \( \infty \)

Check: \( -SV = \frac{2}{2} \left[ \frac{2}{2\pi \varepsilon_0} \int_0^\rho \frac{d\rho}{\rho} \right] \rho = -\frac{2}{2\pi \varepsilon_0} \frac{\rho^2}{2} = -E_r \)

3.9 Now put this line of charge above a conducting plane

Graded

**Grounded**

Guess that the induced charge on the plane has the same field as a line of charge \( \Theta \) a distance \( \beta \) below the sheet.

By symmetry, \( V = 0 \) at sheet. In words, \( V = 0 \) at sheet.
\( S_+^2 = (2-d)^2 + y^2 \quad S_-^2 = (2+d)^2 + y^2 \)

We found \( V_+(s) = -\frac{2}{\text{ar}} \ln \left( \frac{s_+}{a} \right) \). Also \( V(s) = -\frac{2}{\text{ar}} \ln \left( \frac{s}{a} \right) \)

Potential at \( P(y,z) = V_+(s_+) - V_-(s_-) \)

\[
= -\frac{2}{2\pi \varepsilon_0} \left[ \ln s_+ - \ln a - \ln s_- + \ln a \right] = \frac{2}{2\pi \varepsilon_0} \ln \frac{s_-}{s_+}.
\]

NB: \( \ln x = \ln(x^2)^{\frac{1}{2}} = \frac{1}{2} \ln x^2 \)

So \( \ln \frac{s_-}{s_+} = \frac{1}{2} \ln \left( \frac{s_-^2}{s_+^2} \right) \)

and \( V(d) = \frac{2}{2\pi \varepsilon_0} \frac{1}{2} \ln \left[ \frac{(2+d)^2 + y^2}{(2-d)^2 + y^2} \right] \)

\( \sigma = -\varepsilon_0 \frac{\partial V}{\partial n} = -\varepsilon_0 \frac{\partial V}{\partial z} \bigg|_{z=0} = \frac{2}{\text{ar}} \ln \left( \frac{g(2)}{g(2)} \right) \)

\( \frac{\partial}{\partial z} \ln \left( \frac{g(2)}{g(2)} \right) = \frac{1}{g(2)} \frac{\partial}{\partial z} (g) = \frac{1}{g^2} (gf' - fg') = \frac{1}{g} (gf' - fg') \)

\( F' = \frac{2}{\text{ar}^2} [(2+d)^2 + y^2] = 2(2+d), \quad g' = \frac{2}{\text{ar}^2} [(2-d)^2 + y^2] = 2(2-d) \)
